

# The starray Package

## Version 1.9b

Alceu Frigeri\*

February 2025

### Abstract

This package implements vector like 'structures', alike 'C' and other programming languages. It's based on `expl3` and aimed at 'package writers', and not end users. The provided 'functions' are similar the ones provided for property (or sequence, or token) lists. Most of the provided functions have a companion 'branching version'.

## 1 Introduction

The main idea is to have an array like syntax when setting/recovering structured information, e.g. `\starray_get_prop:nn {<student[2].work[3].reviewer[4]>} {<name>}` where "student" is the starray root, "work" is a sub-structure (an array in itself), "reviewer" is a sub-structure of "work" and so on, `<name>` being a property of "reviewer". Moreover one can iterate over the structure, for instance `\starray_get_prop:nn {<student.work.reviewer>} {<name>}` is also a possible reference in which one is using "student's", "work's" and "reviewer's" iterators.

Internally, a `starray` is stored as a collection of property lists. Each `starray` can contain a list of property pairs (key/value as in any `expl3` property lists) and a list of sub-structures. Each sub-structure, at it's turn, can also contain a list of property pairs and a list of sub-structures.

The construction/definition of a `starray` can be done piecewise (a property/sub-structure a time) or with a keyval interface or both, either way, one has to first "create a root starray" (`\starray_new:n`), define it's elements (properties and sub-structures), then instantiate them "as needed". An instance of a `starray` (or one of it's sub-structures) is referred, in this text, as a "term".

---

\*<https://github.com/alceu-frigeri/starray>

Finally, almost all defined functions have a branching version, as per `exp13`: `T`, `F` and `TF` (note: no `_p` variants, see below). For simplicity, in the text below only the `TF` variant is described, as in `\starray_new:nTF`, keep in mind that all 3 variants are defined, e.g. `\starray_new:nT`, `\starray_new:nF` and `\starray_new:nTF`.

**Note:** Could it be implemented with a single property list? It sure could, but at a cost: 1. complexity; 2. access time. The current implementation, albeit also complex, tries to reach a balance between inherent structure complexity, number of used/defined auxiliary property lists and access time.

**Important:** *Expandability*, unfortunately most/all defined functions are not "fully expandable", in particular, most conditional/branching functions aren't, with just a few exceptions (marked with a star ★, as per `exp13` documentation convention).

## 2 Package Options

The package options (`key=value`) are:

`prefix` (default: `l_starray_`). Set the `prefix` used when declaring the property lists associated with any `starray`.

`msg-err` By default, the `starray` package only generates "warnings", with `msg-err` one can choose which cases will generate "package error" messages. There are 3 message classes: 1. `strict` relates to `\starray_new:n` cases (`starray` creation); 2. `syntax` relates to "term syntax" errors (student.work.reviewer in the above examples); finally 3. `reference` relates to cases whereas the syntax is correct but referring to non-existent terms/properties.

<code>none</code>	(default) no package message will raise an error.
<code>strict</code>	will raise an error on <code>strict</code> case alone.
<code>syntax</code>	will raise an error on <code>strict</code> and <code>syntax</code> cases.
<code>reference</code>	will raise an error on <code>strict</code> , <code>syntax</code> and <code>reference</code> cases.
<code>all</code>	will raise an error on all cases.

`msg-suppress` ditto, to suppress classes of messages:

<code>none</code>	(default) no package message will be suppressed.
<code>reference</code>	only <code>reference</code> level messages will be suppressed.
<code>syntax</code>	<code>reference</code> and <code>syntax</code> level messages will be suppressed.
<code>strict</code>	<code>reference</code> , <code>syntax</code> and <code>strict</code> level messages will be suppressed.
<code>all</code>	all messages will be suppressed.

## 3 Creating a starray

---

`\starray_new:n`    `\starray_new:n {<starray>}`  
`\starray_new:nTF`    `\starray_new:nTF {<starray>} {{if-true}} {{if-false}}`

Creates a new `<starray>` or raises a warning if the name is already taken. The declaration (and associated property lists) is global. The given name is referred (in this text) as the `<starray-root>` or just `<root>`.

**Note:** A warning is raised (see 2) if the name is already taken. The branching version doesn't raise any warning.

### 3.1 Conditionals

---

`\starray_if_exist_p:n ★ \starray_if_exist_p:n {<starray>}`  
`\starray_if_exist:nTF ★ \starray_if_exist:nTF {<starray>} {{if-true}} {{if-false}}`  
`\starray_if_valid_p:n ★ \starray_if_valid_p:n {<starray>}`  
`\starray_if_valid:nTF ★ \starray_if_valid:nTF {<starray>} {{if-true}} {{if-false}}`

new: 2023/05/20  
update: 2024/03/28

`\starray_if_exist:nTF` only tests if `<starray>` (the base property) is defined. It doesn't verifies if it really is a `starray`. `\starray_if_valid:nTF` is functionally equivalent since release 1.9. See `\starray_term_syntax:nTF`, section 7, for a more reliable validity test.

**Note:** The predicate versions, `_p`, expand to either `\prg_return_true:` or `\prg_return_false:`

## 4 Defining and initialising a starray structure

---

```
\starray_def_prop:nnn  \starray_def_prop:nnn {{starray-ref}} {{prop-key}} {{initial-value}}
\starray_def_prop:nnnTF \starray_def_prop:nnnTF {{starray-ref}} {{prop-key}} {{initial-value}} {{if-true}}
                                {{if-false}}
```

Adds an entry, `<prop-key>`, to the `<starray-ref>` (see 5.1) definition and set its initial value. If `<prop-key>` is already present its initial value is updated. Both `<prop-key>` and `<initial-value>` may contain any `<balanced text>`. `<prop-key>` is an (`expl3`) property list `<key>` meaning that category codes are ignored.

The definition/assignment of a `<prop-key>` to a `<starray-ref>` is global.

**Note:** A warning is raised (see 2) in case of a `<starray-ref>` syntax/reference error. The branching version doesn't raise any warning.

---

```
\starray_def_structure:nn  \starray_def_struct:nn {{starray-ref}} {{struct-name}}
\starray_def_structure:nnTF \starray_def_struct:nnTF {{starray-ref}} {{struct-name}} {{if-true}} {{if-false}}
```

Adds a sub-structure (a `starray` in itself) to `<starray-ref>` (see 5.1). If `<struct-name>` is already present nothing happens. The definition/assignment of a `<struct-name>` to a `<starray-ref>` is global.

**Note:** Do not use a dot when defining a (sub-)structure name, it might seems to work but it will breaks further down (see 5.1).

**Note 2:** A warning is raised (see 2) in case of a `<starray-ref>` syntax error. The branching version doesn't raise any warning.

---

```
\starray_def_from_keyval:nn  \starray_def_from_keyval:nn {{starray-ref}} {{keyval-lst}}
\starray_def_from_keyval:nnTF \starray_def_from_keyval:nnTF {{starray-ref}} {{keyval-lst}} {{if-true}} {{if-false}}
```

Adds a set of `<keys>` / `<values>` and/or `<structures>` to `<starray-ref>` (see 5.1). The `<keyval-lst>` is pretty straightforward, the construction `<key> . struct` denotes a nested structure :

```
\starray_def_from_keyval:nn {root.substructure}
{
    keyA = valA ,
    keyB = valB ,
    subZ . struct =
    {
        keyZA = valZA ,
        keyZB = valZB ,
    }
    subY . struct =
    {
        keyYA = valYA ,
        keyYB = valYB ,
        subYYY . struct =
        {
            keyYYYa = valYYYa ,
            keyYYYb = valYYYb
        }
    }
}
```

The definitions/assignments to `<starray-ref>` are all global.

**Note:** The non-branching version raises a warning (see 2) in case of a `<starray-ref>` syntax error. The branching version doesn't raise any warning. Also note that, syntax errors on the `<keyval-lst>` might raise low level (TeX) errors.

### 4.1 Fixing an ill-instantiated starray

When instantiating (see 5) a `starray`, the associated structured will be constructed based on it's "current definition" (see 4). A problem that might arise, when one extends the definition of an already instantiated `starray` (better said, if one adds a sub-structure), is a *quark loop* (from `13quark`). To avoid a *quark loop* it is necessary to "fix" the structure of already instantiated terms.

---

```
\starray_fix_terms:n \starray_fix_terms:n {<starray-ref>}
```

The sole purpose of this function is to "fix" the already instantiated terms of a *starray*. Note, this can be an expensive operation depending on the number of terms (it has to crawl over all the terms of an instantiated *starray* adding any missing sub-structure references), but one doesn't need to run it "right away" it is possible to add a bunch of sub-structures and than run this just once.

## 5 Instantiating starray terms

---

```
\starray_new_term:n \starray_new_term:n {<starray-ref>}
\starray_new_term:nn \starray_new_term:nn {<starray-ref>} {<hash>}
\starray_new_term:nTF \starray_new_term:nTF {<starray-ref>} {<if-true>} {<if-false>}
\starray_new_term:nnTF \starray_new_term:nnTF {<starray-ref>} {<hash>} {<if-true>} {<if-false>}
```

---

This create a new *term* (in fact a property list) of the (sub-)struture referenced by *<starray-ref>*. Note that the newly created *term* will have all properties (key/values) as defined by the associated *\starray\_prop\_def:nn {<starray-ref>}*, with the respective "initial values". For instance, given the following

```
\starray_new:n {st-root}

\starray_def_from_keyval:nn {st-root}
{
    keyA = valA ,
    keyB = valB ,
    subZ . struct =
    {
        keyZA = valZA ,
        keyZB = valZB ,
    }
    subY . struct =
    {
        keyYA = valYA ,
        keyYB = valYB ,
        subYYY . struct =
        {
            keyYYYYa = valYYYYa ,
            keyYYYYb = valYYYYb
        }
    }
}

\starray_new_term:n {st-root}
\starray_new_term:n {st-root.subZ}
\starray_new_term:n {st-root.subZ}
\starray_new_term:n {st-root.subY}
\starray_new_term:nn {st-root}{hash-A}
\starray_new_term:n {st-root.subZ}
```

One will have created 6 *terms*:

1. 2 *<st-root>* *terms*
  - (a) the first one with index 1 and
    - i. 2 sub-structures *<subZ>* (indexes 1 and 2)
    - ii. 1 sub-structure *<subY>* (index 1)
  - (b) the second one with indexes 2 and "hash-A" and
    - i. 1 sub-structure *<subZ>* (index 1)

Note that, in the above example, it was used the "implicit" indexing (aka. iterator, see 5.1). Also note that no *term* of kind *<subYYY>* was created.

**Note:** A warning is raised (see 2) in case of a *<starray-ref>* syntax error. The branching version doesn't raise any warning.

## 5.1 referencing terms

When typing a `<starray-ref>` there are 3 cases to consider:

1. structure definition
2. term instantiation
3. getting/setting a property

The first case is the simplest one, in which, one (starting by `<starray-root>`) will use a construct like `<starray-root>.<sub-struct>.<sub-struct>...` For example, an equivalent construct to the one shown in 5 :

```
\starray_new:n {st-root}

\starray_def_struct:nn {st-root}{subZ}

\starray_def_prop:nnn {st-root}{keyA}{valA}
\starray_def_prop:nnn {st-root}{keyB}{valB}

\starray_def_prop:nnn {st-root.subZ}{keyZA}{valZA}
\starray_def_prop:nnn {st-root.subZ}{keyZB}{valZB}

\starray_def_struct:nn {st-root}{subY}
\starray_def_prop:nnn {st-root.subY}{keyYA}{valYA}
\starray_def_prop:nnn {st-root.subY}{keyYB}{valYB}

\starray_def_struct:nn {st-root.subY}{subYYY}
\starray_def_prop:nnn {st-root.subY.subYYY}{keyYYYYA}{valYYYYA}
\starray_def_prop:nnn {st-root.subY.subYYY}{keyYYYYB}{valYYYYB}
```

Note that, all it's needed in order to be able to use `<starray-root>.<sub-A>` is that `<sub-A>` is an already declared sub-structure of `<starray-root>`. The property definitions can be made in any order.

In all other cases, term instantiation, getting/setting a property, one has to address/reference a specific instance/term, implicitly (using iterators) or explicitly using indexes. The general form, of a `<starray-ref>`, is:

`<starray-root>(<idx>.<sub-A>(<idxA>.<sub-B>(<idxB>)`

In the case of term instantiation the last `<sub->` cannot be indexed, after all one is creating a new term/index. Moreover, all `<idx>` are optional like:

`<starray-root>.<sub-A>(<idxA>.<sub-B>)`

in which case, one is using the "iterator" of `<starray-root>` and `<sub-B>` (more later, but keep in mind the `<sub-B>` iterator is the `<sub-B>` associated with the `<sub-A>(<idxA>)`).

Since one has to explicitly instantiate all (sub)terms of a starray, one can end with a highly asymmetric structure. Starting at the `<starray-root>` one has a first counter (representing, indexing the root structure terms), then for all sub-strutures of `<starray-root>` one will have an additional counter for every term of `<starray-root>` !

So, for example:

```
\starray_new:n {st-root}
\starray_def_struct:nn {st-root}{subZ}
\starray_def_struct:nn {st-root}{subY}
\starray_def_struct:nn {st-root.subY}{subYYY}

\starray_new_term:n {st-root}
\starray_new_term:n {st-root.subZ}
\starray_new_term:n {st-root.subZ}
\starray_new_term:n {st-root.subY}
\starray_new_term:n {st-root.subY}
\starray_new_term:n {st-root.subY.subYYY}
\starray_new_term:n {st-root.subY}

\starray_new_term:n {st-root}
\starray_new_term:n {st-root.subZ}
\starray_new_term:n {st-root.subZ}
\starray_new_term:n {st-root.subY}
```

One has a single `<st-root>` iterator (pointing to one of the 3 `<st-root>` terms), then 3 "`<subZ>` iterators", in fact, one `<subZ>` iterator for each `<st-root>` term. Likewise there are 3 "`<subY>` iterators" and 4 (four) "`<subYYY>` iterators" one for each instance of `<subY>`.

Every time a new term is created/instantiated, the corresponding iterator will points to it,

which allows the notation used in this last example, keep in mind that one could instead, using explicit indexes:

```
\starray_new:n {st-root}
\starray_def_struct:nn {st-root}{subZ}
\starray_def_struct:nn {st-root}{subY}
\starray_def_struct:nn {st-root.subY}{subYYY}

\starray_new_term:n {st-root}
\starray_new_term:n {st-root[1].subZ}
\starray_new_term:n {st-root[1].subZ}
\starray_new_term:n {st-root[1].subY}
\starray_new_term:n {st-root[1].subY}
\starray_new_term:n {st-root[1].subY[2].subYYY}
\starray_new_term:n {st-root[1].subY}

\starray_new_term:n {st-root}
\starray_new_term:n {st-root[2].subZ}
\starray_new_term:n {st-root[2].subZ}
\starray_new_term:n {st-root[2].subY}
```

Finally, observe that, when creating a new term, one has the option to assign a "hash" to it, in which case that term can be referred to using an iterator, the explicit index or the hash:

```
\starray_new:n {st-root}
\starray_def_struct:nn {st-root}{subZ}
\starray_def_struct:nn {st-root}{subY}
\starray_def_struct:nn {st-root.subY}{subYYY}

\starray_new_term:nn {st-root}{hash-A}
\starray_new_term:n {st-root.subZ}
\starray_new_term:n {st-root[1].subZ}
\starray_new_term:n {st-root[hash-A].subZ}
```

Will create 3 `<subZ>` terms associated with the first (index = 1) `(st-root)`.

## 5.2 iterators

---

<code>\starray_set_iter:nn</code>	<code>\starray_set_iter:nn {&lt;starray-ref&gt;} {&lt;int-val&gt;}</code>
<code>\starray_set_iter:nnTF</code>	<code>\starray_set_iter:nTF {&lt;starray-ref&gt;} {&lt;int-val&gt;} {&lt;if-true&gt;} {&lt;if-false&gt;}</code>
<code>\starray_reset_iter:nn</code>	<code>\starray_reset_iter:nn {&lt;starray-ref&gt;}</code>
<code>\starray_reset_iter:nnTF</code>	<code>\starray_reset_iter:nTF {&lt;starray-ref&gt;} {&lt;if-true&gt;} {&lt;if-false&gt;}</code>
<code>\starray_next_iter:nn</code>	<code>\starray_next_iter:nn {&lt;starray-ref&gt;}</code>
<code>\starray_next_iter:nnTF</code>	<code>\starray_next_iter:nTF {&lt;starray-ref&gt;} {&lt;if-true&gt;} {&lt;if-false&gt;}</code>

---

Those functions allows to `set` an iterator to a given `<int-val>`, `reset` it (i.e. assign 1 to the iterator), or increase the iterator by one. An iterator might have a value between 1 and the number of instantiated terms (if the given (sub-)structure was already instantiated). If the (sub-)structure hasn't been instantiated yet, the iterator will always end being set to 0. The branching versions allows to catch those cases, like trying to set a value past its maximum, or a value smaller than one.

**Important:** Please observe that, when setting/resetting/incrementing the iterator of a (sub-)structure, all "descending" iterators will be also be reset.

**Note:** A warning is raised (see 2) in case of a `<starray-ref>` syntax error. The branching version doesn't raise any warning.

```

\starray_new:n {st-root}
\starray_def_struct:nn {st-root}{subZ}
\starray_def_struct:nn {st-root}{subY}
\starray_def_struct:nn {st-root.subY}{subYYY}

\starray_new_term:n {st-root}
\starray_new_term:n {st-root.subZ}
\starray_new_term:n {st-root.subZ}
\starray_new_term:n {st-root.subY}
\starray_new_term:n {st-root.subY.subYYY}
\starray_new_term:n {st-root.subY.subYYY}
\starray_new_term:n {st-root.subY}
\starray_new_term:n {st-root.subY.subYYY}
\starray_new_term:n {st-root.subY.subYYY}
\starray_new_term:n {st-root}
\starray_new_term:n {st-root.subZ}
\starray_new_term:n {st-root.subZ}
\starray_new_term:n {st-root.subY}
\starray_new_term:n {st-root.subY.subYYY}
\starray_new_term:n {st-root.subY.subYYY}
\starray_new_term:n {st-root.subY}
\starray_new_term:n {st-root.subY.subYYY}
\starray_new_term:n {st-root.subY.subYYY}

\starray_set_prop:nnn {st-root.subY.subYYY}{key}{val}
\starray_set_prop:nnn {st-root[2].subY[2].subYYY[2]}{key}{val}

\starray_reset_iter:n {st-root[2].subY}

\starray_set_prop:nnn {st-root.subY.subYYY}{key}{val}
\starray_set_prop:nnn {st-root[2].subY[1].subYYY[1]}{key}{val}

```

Before the reset  $\langle st\text{-}root.\text{subY}.\text{subYYY} \rangle$  was equivalent to  $\langle st\text{-}root[2].\text{subY}[2].\text{subYYY}[2] \rangle$ , given that each iterator was pointing to the "last term", since the reset was of the  $\langle \text{subY} \rangle$  iterator, only it and the descending ones (in this example just  $\langle \text{subYYY} \rangle$ ) were reseted, and therefore  $\langle st\text{-}root.\text{subY}.\text{subYYY} \rangle$  was then equivalent to  $\langle st\text{-root}[2].\text{subY}[1].\text{subYYY}[1] \rangle$

---

```

\starray_set_iter_from_hash:nn  \starray_set_iter_from_hash:nn {\langle starray-ref \rangle} {\langle hash \rangle}
\starray_set_iter_from_hash:nnTF \starray_set_iter_from_hash:nnTF {\langle starray-ref \rangle} {\langle hash \rangle} {\langle if-true \rangle} {\langle if-false \rangle}

```

---

new: 2023/11/04

---

`\starray_set_iter_from_hash:nn` will set iter based on the `\langle hash \rangle` used when instantiating a term (see 5 ).

**Note:** A warning is raised (see 2) in case of a `\langle starray-ref \rangle` syntax error or invalid `\langle hash \rangle`. The branching version doesn't raise any warning.

---

```

\starray_get_iter:n   \starray_get_iter:n {\langle starray-ref \rangle}
\starray_get_iter:nN  \starray_get_iter:nN {\langle starray-ref \rangle} {\langle int-var \rangle}
\starray_get_iter:nNTF \starray_get_iter:nNTF {\langle starray-ref \rangle} {\langle int-var \rangle} {\langle if-true \rangle} {\langle if-false \rangle}

```

---

`\starray_get_iter:n` will type in the current value of a given iterator, whilst the other two functions will save it's value in a integer variable (`exp13`).

**Note:** A warning is raised (see 2) in case of a `\langle starray-ref \rangle` syntax error. The branching version doesn't raise any warning.

---

```

\starray_parsed_get_iter: ★ \starray_parsed_get_iter:

```

---

new: 2023/05/20

---

`\starray_parsed_get_iter:` will place in the current iterator's value, using `\int_use:N`, of the last parsed term in the input stream.

**Warning:** This can be used after any command which 'parses a term', for instance `\starray_term_syntax:n`, see section 7, but it only makes sense (and returns a reliable/meaningful result) IF the last parser operation was successfully executed.

---

```
\starray_parsed_get_iter:NN ★ \starray_parsed_get_iter:NN {⟨parsed-refA⟩} {⟨parsed-refB⟩}
```

new: 2023/11/28

`\starray_parsed_get_iter:` will place in the current iterator's value associated with `⟨parsed-refA⟩` and `⟨parsed-refB⟩`, using `\int_use:N`, in the input stream.

**Warning:** `⟨parsed-refA⟩` and `⟨parsed-refB⟩` are the values returned by `\starray_term_syntax:nNN`.

---

```
\starray_get_cnt:n   \starray_get_cnt:n {⟨starray-ref⟩}
\starray_get_cnt:nN \starray_get_cnt:nN {⟨starray-ref⟩} {⟨integer⟩}
\starray_get_cnt:nTF \starray_get_cnt:nTF {⟨starray-ref⟩} {⟨integer⟩} {⟨if-true⟩} {⟨if-false⟩}
```

`\starray_get_cnt:n {⟨starray-ref⟩}` will type in the current number of terms of a given (sub-)structure, whilst the other two functions will save it's value in a integer variable (`exp13`).

**Note:** A warning is raised (see 2) in case of a `⟨starray-ref⟩` syntax error. The branching version doesn't raise any warning.

---

```
\starray_parsed_get_cnt: ★ \starray_parsed_get_cnt:
```

new: 2023/05/20

`\starray_parsed_get_cnt:` will place the current number of terms, using `\int_use:N`, of the last parsed term, in the input stream.

**Warning:** This can be used after any command which 'parses a term', for instance `\starray_term_syntax:n`, see section 7, but it only makes sense (and returns a reliable/meaningful result) IF the last parser operation was successfully executed.

---

```
\starray_parsed_get_cnt:NN ★ \starray_parsed_get_cnt:NN {⟨parsed-refA⟩} {⟨parsed-refB⟩}
```

new: 2023/11/28

`\starray_parsed_get_cnt:` will place in the current number of terms associated with `⟨parsed-refA⟩` and `⟨parsed-refB⟩`, using `\int_use:N`, in the input stream.

**Warning:** `⟨parsed-refA⟩` and `⟨parsed-refB⟩` are the values returned by `\starray_term_syntax:nNN`.

---

```
\starray_iterate_over:nn   \starray_iterate_over:nn {⟨starray-ref⟩} {⟨code⟩}
\starray_iterate_over:nnTF \starray_iterate_over:nnTF {⟨starray-ref⟩} {⟨code⟩} {⟨if-true⟩} {⟨if-false⟩}
```

new: 2023/11/04

`\starray_iterate_over:nn` will reset the `⟨starray-ref⟩` iterator, and then execute `⟨code⟩` for each valid value of `iter`. At the loop's end, the `⟨starray-ref⟩` iterator will point to the last element of it. The `⟨if-true⟩` is executed, at the loop's end if there is no syntax error, and the referenced structure was properly instantiated. Similarly `⟨if-false⟩` is only execute if a syntax error is detected or the referenced structure wasn't properly instantiated

**Note:** `\starray_iterate_over:nn` Creates a local group, so that one can recurse over sub-structures. Be aware, then, that `⟨code⟩` is executed in said local group.

**Note:** A warning is raised (see 2) in case of a `⟨starray-ref⟩` syntax error or the structure wasn't yet instantiated. The branching version doesn't raise any warning.

## 6 Changing and recovering starray properties

---

```
\starray_set_prop:nnn   \starray_set_prop:nnn {⟨starray-ref⟩} {⟨prop-key⟩} {⟨value⟩}
\starray_set_prop:nnV   \starray_set_prop:nnV {⟨starray-ref⟩} {⟨prop-key⟩} {⟨value⟩}
\starray_set_prop:nnnTF \starray_set_prop:nnnTF {⟨starray-ref⟩} {⟨prop-key⟩} {⟨value⟩} {⟨if-true⟩} {⟨if-false⟩}
\starray_set_prop:nnVTF \starray_set_prop:nnVTF {⟨starray-ref⟩} {⟨prop-key⟩} {⟨value⟩} {⟨if-true⟩} {⟨if-false⟩}
\starray_gset_prop:nnn  \starray_gset_prop:nnn {⟨starray-ref⟩} {⟨prop-key⟩} {⟨value⟩}
\starray_gset_prop:nnV  \starray_gset_prop:nnV {⟨starray-ref⟩} {⟨prop-key⟩} {⟨value⟩}
\starray_gset_prop:nnnTF \starray_gset_prop:nnnTF {⟨starray-ref⟩} {⟨prop-key⟩} {⟨value⟩} {⟨if-true⟩} {⟨if-false⟩}
\starray_gset_prop:nnVTF \starray_gset_prop:nnVTF {⟨starray-ref⟩} {⟨prop-key⟩} {⟨value⟩} {⟨if-true⟩} {⟨if-false⟩}
```

Those are the functions that allow to (g)set (change) the value of a term's property. If the

`<prop-key>` isn't already present it will be added just for that term `<starray-ref>`. The `<nnV>` variants allow to save any variable like a token list, property list, etc...

**Note:** A warning is raised (see 2) in case of a `<starray-ref>` syntax error. The branching version doesn't raise any warning.

---

```
\starray_set_from_keyval:nn      \starray_set_from_keyval:nnn {<starray-ref>} {<keyval-lst>}
\starray_set_from_keyval:nnTF    \starray_set_from_keyval:nnnTF {<starray-ref>} {<keyval-lst>} {<if-true>}
\starray_gset_from_keyval:nn     {<if-false>}
\starray_gset_from_keyval:nnTF   \starray_gset_from_keyval:nnn {<starray-ref>} {<keyval-lst>}
                               \starray_gset_from_keyval:nnnTF {<starray-ref>} {<keyval-lst>} {<if-true>}
                               {<if-false>}
```

---

it is possible to set a collection of properties using a key/val syntax, similar to the one used to define a `starray` from keyvals (see 4), with a few distinctions:

1. when referring a (sub-)structure one can either explicitly use an index, or
2. implicitly use it's iterator
3. if a given key isn't already presented it will be added only to the given term

Note that, in the following example, TWO iterators are being used, the one for `<st-root>` and then `<subY>`.

```
\starray_set_from_keyval:nn {st-root}
{
  keyA = valA ,
  keyB = valB ,
  subZ[2] =
  {
    keyZA = valZA ,
    keyZB = valZB ,
  }
  subY =
  {
    keyYA = valYA ,
    keyYB = valYB ,
    subYYY[1] =
    {
      keyYYYYa = valYYYYa ,
      keyYYYYb = valYYYYb
    }
  }
}
```

Also note that the above example is fully equivalent to:

```
\starray_set_prop:nnn {st-root} {keyA} {valA}
\starray_set_prop:nnn {st-root} {keyB} {valB}
\starray_set_prop:nnn {st-root.subZ[2]} {keyZA} {valZA}
\starray_set_prop:nnn {st-root.subZ[2]} {keyZB} {valZB}
\starray_set_prop:nnn {st-root.subY} {keyYA} {valYA}
\starray_set_prop:nnn {st-root.subY} {keyYB} {valYB}
\starray_set_prop:nnn {st-root.subY.subYYY[1]} {keyYYYYa} {valYYYYa}
\starray_set_prop:nnn {st-root.subY.subYYY[1]} {keyYYYYb} {valYYYYb}
```

---

```
\starray_get_prop:nn      \starray_get_prop:nn {<starray-ref>} {<key>}
\starray_get_prop:nnN     \starray_get_prop:nnN {<starray-ref>} {<key>} {<tl-var>}
\starray_get_prop:nnNTF   \starray_get_prop:nnNTF {<starray-ref>} {<key>} {<tl-var>} {<if-true>} {<if-false>}
```

`\starray_get_prop:nn {<starray-ref>} {<key>}` places the value of `<key>` in the input stream.  
`\starray_get_prop:nnN {<starray-ref>} {<key>} {<tl-var>}` recovers the value of `<key>` and places it in `<tl-var>` (a token list variable), this is specially useful in conjunction with `\starray_set_prop:nnV`, whilst the `\starray_get_prop:nnNTF` version branches accordingly.

**Note:** In case of a syntax error, or `<key>` doesn't exist, an empty value is left in the stream (or `<tl-var>`).

**Note:** A warning is raised (see 2) in case of a `<starray-ref>` syntax error. The branching version doesn't raise any warning.

---

```
\starray_parsed_get_prop:n ★ \starray_parsed_get_prop:n {⟨key⟩}
```

new: 2023/05/20

`\starray_parsed_get_prop:n {⟨key⟩}` places the value of `⟨key⟩`, if it exists, from the last parsed term, in the input stream.

**Warning:** This can be used after any command which 'parses a term', for instance `\starray_term_syntax:n`, see section 7, but it only makes sense (and returns a reliable/meaningful result) IF the last parser operation was successfully executed.

---

```
\starray_parsed_get_prop:NNn ★ \starray_parsed_get_prop>NNn {⟨parsed-refA⟩} {⟨parsed-refB⟩} {⟨key⟩}
```

new: 2023/11/28

`\starray_parsed_get_prop>NNn` places the value of `⟨key⟩`, if it exists, associated with `⟨parsed-refA⟩` and `⟨parsed-refB⟩`.

**Warning:** `⟨parsed-refA⟩` and `⟨parsed-refB⟩` should be the values returned by `\starray_term_syntax:nNN`.

## 7 Additional Commands and Conditionals

---

```
\starray_if_in:nnTF \starray_if_in:nnTF {⟨starray-ref⟩} {⟨key⟩} {⟨if-true⟩} {⟨if-false⟩}
```

The `\starray_if_in:nnTF {⟨starray-ref⟩} {⟨key⟩} {⟨...⟩} {⟨...⟩}` tests if a given `⟨key⟩` is present.

---

```
\starray_term_syntax:n \starray_term_syntax:n {⟨starray-ref⟩}
```

---

```
\starray_term_syntax:nTF \starray_term_syntax:nTF {⟨starray-ref⟩} {⟨if-true⟩} {⟨if-false⟩}
```

new: 2023/05/20

This will just parse a `⟨starray-ref⟩` reference, and set interval variables so that commands like `\starray_parsed_` can be used.

**Warning:** The main idea is to allow some expandable commands, but be aware that all `\starray_` commands that use a `⟨starray-ref⟩` use the very same parser variables. In case one needs are more permanent/resilient `starray` reference, one should use the `\starray_term_syntax:nNN` variant.

**Note:** A warning is raised (see 2) in case of a `⟨starray-ref⟩` syntax error. The branching version doesn't raise any warning.

---

```
\starray_term_syntax:nNN \starray_term_syntax:nNN {⟨starray-ref⟩} {⟨parsed-refA⟩} {⟨parsed-refB⟩}
```

---

```
\starray_term_syntax:nNTF \starray_term_syntax:nNTF {⟨starray-ref⟩} {⟨parsed-refA⟩} {⟨parsed-refB⟩} {⟨if-true⟩}
```

new: 2023/11/28

Similar to the ones above (`\starray_term_syntax:n`). `⟨parsed-refA⟩` and `⟨parsed-refB⟩` (assumed to be two token list vars, `{tl-var}`) will receive two 'internal references' that can be used in commands like `\starray_parsed_...:NN` which expects such 'references', without having to worry about using another `\starray_` command.

**Note:** Once correctly parsed, `⟨parsed-refA⟩` and `⟨parsed-refB⟩` can be used at 'any time' (by those few `\starray_parsed_...:NN` associated commands).

**Note:** A warning is raised (see 2) in case of a `⟨starray-ref⟩` syntax error (in which case `⟨parsed-refA⟩` and `⟨parsed-refB⟩` will not hold a valid value). The branching version doesn't raise any warning.

---

```
\starray_parsed_if_in_p:n ★ \starray_parsed_if_in_p:nTF {⟨key⟩}
```

---

```
\starray_parsed_if_in:nTF ★ \starray_parsed_if_in:nTF {⟨key⟩} {⟨if-true⟩} {⟨if-false⟩}
```

new: 2023/05/20

This will test if the given `key` is present in the "last parsed term".

**Note:** The predicate version, `_p`, expands to either `\prg_return_true:` or `\prg_return_false::`.

**Warning:** This can be used after any command which 'parses a term', for instance `\starray_term_syntax:n`, but it only makes sense (and returns a reliable/meaningful result) IF the last parser operation was successfully executed.

---

```
\starray_parsed_if_in_p:NNn ★ \starray_parsed_if_in_p:nTF {⟨parsed-refA⟩} {⟨parsed-refB⟩} {⟨key⟩}
\starray_parsed_if_in>NNnTF ★ \starray_parsed_if_in:nTF {⟨parsed-refA⟩} {⟨parsed-refB⟩} {⟨key⟩} {⟨if-true⟩}
{⟨if-false⟩}
```

new: 2023/11/28

---

This will test if the given `key` is present/associated with `⟨parsed-refA⟩` and `⟨parsed-refB⟩`.

**Note:** The predicate version, `_p`, expands to either `\prg_return_true:` or `\prg_return_false::`.

**Warning:** `⟨parsed-refA⟩` and `⟨parsed-refB⟩` should be the values returned by `\starray_term_syntax:nNN`.

---

```
\starray_get_unique_id:nN \starray_get_unique_id:nN {⟨starray-ref⟩} {⟨tl-var⟩}
\starray_get_unique_id:nNTF \starray_get_unique_id:nNTF {⟨starray-ref⟩} {⟨tl-var⟩}
```

---

new: 2024/03/10

---

Gets an 'unique ID' for a given `⟨starray-ref⟩ term`, it should help defining/creating uniquely identified auxiliary structures, like auxiliary property or sequence lists, since one can't (better said shouldn't, as per l3kernel) store an anonymous property/sequence list using V-expansion.

**Note:** A warning is raised (see 2) in case of a `⟨starray-ref⟩` syntax error. The branching version doesn't raise any warning.

## 8 Showing (debugging) starrays

---

```
\starray_show_def:n \starray_show_def:n {⟨starray-ref⟩}
\starray_show_def_in_text:n \starray_show_def_in_text:n {⟨starray-ref⟩}
```

---

Displays the `⟨starray⟩` structure definition and initial property values in the terminal or directly in text.

---

```
\starray_show_terms:n \starray_show_terms:n {⟨starray-ref⟩}
\starray_show_terms_in_text:n \starray_show_terms_in_text:n {⟨starray-ref⟩}
```

---

Displays the `⟨starray⟩` instantiated terms and current property values in the terminal or directly in text.
